    - Absorption Filters
  - Monochromators
Spectral Considerations

\[ n(\lambda) = \frac{\text{speed in vacuum}}{c} \]
\[ \frac{\text{speed in medium}}{v(\lambda)} \]

- \( n \), will always be greater than one
- So, the index is different for different wavelengths
- Therefore, the amount of refraction is different
- This effect is called chromatic dispersion
Spectral Considerations

Blue Lags Red

Oblique angle, colors separate (Snell's Law)

Dispersing Prism

\[ \delta \] is the deviation angle
Applications of Dispersing Prisms

- **Spectro-scope**
  - Used for view a spectrum

- **Spectro-meter**
  - Is equipped for measuring a spectrum

- **Spectro-graph**
  - Is built for photography

- **Spectro-photometer**
  - Photocell takes the place of the photographic film

- **Mono-chromator**
  - Instrument for selecting light of different wavelengths
Wave Optics

  - Grating equation
  - Resolution
  - Types of gratings

- **Thin Films**
  - Plane-parallel plates
  - Faby-Perot interferometer
  - Newton’s rings
  - Interference filters
  - Antireflection coatings
Interference

- Refers to the phenomenon that waves, under certain conditions, intensify or weaken each other.

- Interference is inseparably tied to that of diffraction (as we will see).
Superposition of Waves

- Consider the following 2 cases

- The superposition of waves of
  1. Equal phase and frequency
  2. Constant phase difference
Equal phase and frequency

\[ A = A_1 + A_2 + \ldots + A_N \]

Irradiance of light is proportional to the square of the amplitude

\[ \text{Irradiance} \propto A^2 \]

\[ E \propto A^2 \]

\[ E \propto \left( A_1 + A_2 + A_3 + \cdots + A_N \right)^2 \]
The resultant wave can be found by using complex algebra

\[ A_1 = A_1 e^{i(\omega t + \phi_1)} \quad \rightarrow \quad RE = A_1 \cos(\omega t + \phi_1) \]
\[ A_2 = A_2 e^{i(\omega t + \phi_2)} \]

\[ A = A_1 + A_2 \]
\[ A^2 = A_1^2 + A_2^2 + 2A_1A_2 \cos(\phi_1 - \phi_2) \quad \text{We want irradiance, i.e.,} \ A^2 \]
Interference Fringes

\[ A^2 = A_1^2 + A_2^2 + 2A_1A_2 \cos(\phi_1 - \phi_2) \]
\[ E \propto A^2 \]
\[ E = E_1 + E_2 + 2\sqrt{E_1E_2} \cos \delta \]

We can rewrite the irradiance with substitution

When \( \delta = 0 \) (in phase), get maximum amount of light

\[ E_{\text{max}} = E_1 + E_2 + 2\sqrt{E_1E_2} \]

Furthermore, if \( E_1 = E_2 \) (e.g., coming from a LASER source)

\[ E_{\text{max}} = 4E_1 \] (constructive interference)
Interference Fringes

When \( \delta = 180 \) (out of phase), get minimum amount of light

\[
E_{\text{min}} = E_1 + E_2 - 2\sqrt{E_1E_2}
\]

If \( E_1 = E_2 \)

\[
E_{\text{min}} = 0 \quad \text{(destructive interference)}
\]

In general, assuming \( E_1 = E_2 = E_0 \)

\[
E = E_0 + E_0 + 2E_0 \cos \delta
\]

\[
E = 2E_0(1 + \cos \delta)
\]

\[
\cos^2 \theta = \frac{1}{2}(1 + \cos 2\theta)
\]

\[
E = 4E_0 \cos^2\left(\frac{\delta}{2}\right)
\]

Alternating bright/dark fringes called interference

Diagram showing graph of \( E(\delta) \) with bright and dark fringes spaced by \( 1\lambda \).
Young’s Double-Slit Experiment

2-Beam Interference (monochromatic source)
Assume separation of slits is << D (i.e., Fraunhofer, or far field)

Relative Brightness
- 0th-order maximum
- 1st-order maximum
- 2nd-order maximum

Slits widths are not much greater in width than the wavelength of light
Young’s Double-Slit Experiment

Interference  Diffraction

2^{nd}-order maximum
1^{st}-order maximum
0^{th}-order maximum
Young’s Double-Slit Experiment

- When the path difference is zero, we have 0\textsuperscript{th} order maximum.
- But a maximum will occur whenever the path difference, $\Gamma$, is one wavelength or an integral multiple of a wavelength, $m\lambda$ (remember the phase difference from before)
- Let's define the path difference as:

$$\Gamma = m\lambda$$

The integer $m$ is called the order of interference.
Young’s Double-Slit Experiment

Position of the Maximum (from geometry)

\[ \sin \theta = \frac{\Gamma}{d} = \frac{m\lambda}{d} \]

\[ d \sin \theta = m\lambda \quad m = 0, 1, 2... \]

\( \phi \) difference depends on angle

(We will see that this becomes the grating equation)

Positions of the Minimum

-Whenever one of the contributions has shifted in phase by \( \lambda/2 \), that is

\[ d \sin \theta = (m - \frac{1}{2})\lambda \quad m = 1, 2... \]

In double-slit interference there is no zeroth-order minimum (i.e., \( m=0 \))
Diffraction

- When light passes through a narrow slit, it spreads out more than what could be accounted for by geometric construction.

- Diffraction can be defined as any departure from the predictions of geometric optics.
What is a Diffraction Grating?

- Extension of Young’s double slit
- Is based on both diffraction and interference
- Uses an arrangement which is equivalent in its action to a number of parallel equidistant slits of the same width
- Move from 2-slit to N-slit interference problem
Intensity Distribution from and Ideal Grating

- So far we have considered only the separation, $d$, of the slits.
- But the slits also have a finite width, $s$.
- This significantly changes the intensity distribution behind the grating.

- This leads to a diffraction contribution due to the finite width, $s$ of the slits, in addition to interference effects from the separation, $d$. 
Ideal Grating

Eq. (1) \[ E_{\theta} = E_0 \frac{\sin^2\left(\frac{\pi}{\lambda} s \sin \theta \right)}{\left(\frac{\pi}{\lambda} s \sin \theta \right)^2} \]

- Diffraction contribution of single slit.
- Due to finite width, \( s \), of the slits.

Eq. (2) \[ E_{\theta} = E_0 \frac{\sin^2\left( N \frac{\pi}{\lambda} d \sin \theta \right)}{\sin^2\left(\frac{\pi}{\lambda} d \sin \theta \right)} \]

- This is the interference contribution.
- Due to multiplicity of slits separated by \( d \)
The total, actual pattern behind the grating is found by multiplying the two contributions.

\[ E_\theta = E_0 \frac{\sin^2 D \sin^2 NI}{D^2 \sin^2 I} \]

-One contribution is being modulated by the other
-Diffraction is modulating the interference term

Where,

\[ D = \frac{\pi b \sin \theta}{\lambda} \]

Pertinent term in the diffraction contribution

\[ I = \frac{\pi d \sin \theta}{\lambda} \]

Pertinent term in the interference contribution
N-Slits

- When you increase number of slits, $N$, the interference maxima narrows.
- At the same time, the secondary maxima, $SM$, between them are suppressed.
Formation of Spectra by Grating

Principal maxima are called spectrum lines.
Transmission Diffraction Grating

Principal uses are in spectroscopy, e.g., Transmission Grating Spectrograph, (similar to prism spectrograph)

(Light source is assumed to emit two wavelengths)
(Light source is assumed to emit two wavelengths)

Actually would get a “line spectrum”
Diffraction Gratings - Formally

As in double-slit interference from before:

\[ d \sin \theta_r = m \lambda \]

\( d \) = the distance between the centers of any two adjacent slits
\( \theta_r \) = the angle through which the light is diffracted
\( m \) = order
\( \lambda \) = wavelength

This is the same equation derived for double-slit maxima or the grating equation for normal incidence (e.g., can compute the angles at which the PM are formed)
General Diffraction Grating Eqn.

If light is incident at an angle $\theta_i$, then

$$d(\sin \theta_i \pm \sin \theta_r) = m\lambda$$

Eq. (5)

Which is the more complete grating equation
(-) indicates $\theta_r$ and $\theta_i$ are on opposite sides of the grating normal.
(+) indicates $\theta_r$ and $\theta_i$ are on same side of grating normal
Diffraction Orders

Line Spectrum

Diffraction Orders

Positive orders

Negative orders

Grating normal

$\alpha$

$m = 0$
Overlapping Diffracted Spectra

- Problem with multiple order behavior is that successive spectra overlap.

Light for $\lambda = 100, 200, 300$ nm in the 2nd order is diffracted in the same direction as light $\lambda = 200, 400, 600$ nm in the 1st order.

Prevented by filtering or sometimes called order sorting.
6.9 Spectro-radiometry

- Spectral Considerations
  - Chromatic dispersion
  - Diffraction grating theory

- Spectrometer
  - Filter Spectrometer
  - Prism Spectrometer
  - Grating Spectrometer
  - Applications and numerical example

- Diffraction Grating Types
  - Plane Grating
  - Concave Grating

- Wavelength Selectors
  - Filters
    - Interference Filters
    - Interference Wedges
    - Absorption Filters
  - Monochromators
Spectrometer

- A spectroscopic instrument that may scan wavelengths individually or the entire spectra simultaneously.

- It may employ a **prism** or **grating** for means of dispersing incident light.
Prism Spectrometer

- Using prism and dispersion
- Light must be collimated onto prism
Grating Spectrometer

- High dispersion using compact element
- The element used in such a systems is:
  - A diffraction grating
- Comes in many configurations
Spectrometer Applications

- Is used in spectroscopy (the study of spectra)
  - Producing spectral lines
  - Measuring their wavelengths and intensities

- Astronomy
  - Most large telescopes have spectrographs
  - Measure chemical compositions of objects
  - Measure velocities from the Doppler shift of spectral lines

- Remote Sensing
  - Imaging spectrometers (hyperspectral data)
  - Field spectroscopy of natural and man-made objects
6.9 Spectro-radiometry

- Spectral Considerations
  - Chromatic dispersion
  - Diffraction grating theory

- Spectrometer
  - Filter Spectrometer
  - Prism Spectrometer
  - Grating Spectrometer
  - Applications and numerical example

- Diffraction Grating Types
  - Plane Grating
  - Concave Grating

- Wavelength Selectors
  - Filters
    - Interference Filters
    - Interference Wedges
    - Absorption Filters
  - Monochromators
Diffraction Grating Types

- Reflection grating
  - Grating superimposed on a reflective surface
- Transmission grating
  - Grating superimposed on a transparent surface
Diffraction by Plane Grating

-Think of each grating groove as being a very small, slit-shaped source of diffracted light
-Angles are measured FROM the grating normal TO the beam

Incident light, $\alpha$, diffracted light, $\beta_{-1}$, $\beta_0$, $\beta_1$
Plane Gratings

- Illuminated by collimated light
- No aberrations introduced into the diffracted wave fronts

Czerny-Turner

- Large mirror serves as both collimator and camera
- Use is limited since stray light and aberrations are difficult to control

Ebert-Fastie
Plane Gratings

- Illuminated by converging light
- Aberrations introduced into the diffracted wavefronts
- Good for low-resolution applications
- Simplest and least expensive design

Monk-Gillieson

- Autocollimating configuration

Littrow
Concave Gratings

- Illuminated by point source on circle
- Spectra on circle is free from defocus and primary coma at all wavelengths
Concave Gratings

- Illuminated with collimated light

Wadsworth spectrograph

- Forms a spectrum on a flat surface
- Ideal for use in linear detector array instruments

Flat-field spectrgraph
6.9 Spectro-radiometry

- Spectral Considerations
  - Chromatic dispersion
  - Diffraction grating theory

- Spectrometer
  - Filter Spectrometer
  - Prism Spectrometer
  - Grating Spectrometer
  - Applications and numerical example

- Diffraction Grating Types
  - Plane Grating
  - Concave Grating

- Wavelength Selectors
  - Filters
    - Interference Filters
    - Interference Wedges
    - Absorption Filters
  - Monochromators

- Interferometers
Wavelength Selectors

- Ideally want to isolate 1 wavelength
- End up with a narrow band
- Two types encountered
  - Filters
    - Absorption
      - Limited to VIS
    - Interference (Faby-Perot)
      - Used in UV, VIS, IR
  - Monochromators

FWHM: 10nm and 50nm
Monochromators

• Come in both prism and grating types
• At output we get rectangular images of the entrance slit
